## Exercise 7

### Task 1

Given an ordinary differential equation

$$y' = f(t, y), \quad y(t_0) = y_0, \quad t_0 \leq t \leq t_{\text{end}}. \quad (1)$$

You can assume that  $f$  satisfies the Lipschitz condition

$$\|f(t, y) - f(t, \tilde{y})\| \leq L\|y - \tilde{y}\|.$$

A *one-step method* for solving this differential equation can be described by

$$y_{n+1} = y_n + h\Phi(t_n, y_n; h), \quad n = 0, 1, \dots, N-1, \quad h = \frac{t_{\text{end}} - t_0}{N} \quad (2)$$

Assume the following:

- The local truncation error given by

$$d_{n+1} = y(t_{n+1}) - y(t_n) - h\Phi(t_n, y(t_n); h)$$

satisfies

$$\|d_{n+1}\| \leq Dh^{p+1}$$

where  $D$  is a positive constant.

- The function  $\Phi$  is Lipschitz continuous, with Lipschitz constant  $M$ , i.e.

$$\|\Phi(t_n, y; h) - \Phi(t_n, \tilde{y}; h)\| \leq M\|y - \tilde{y}\|. \quad (3)$$

- a) Show that in this case, the global error in  $t_{\text{end}}$  satisfies

$$\|e_N\| = \|y(t_{\text{end}}) - y_N\| \leq Ch^p,$$

where  $C$  is a positive constant depending on  $M$ ,  $D$  and the interval  $t_{\text{end}} - t_0$ .

- b) Assume that a two-stage explicit Runge–Kutta method given by the Butcher tableau

$$\begin{array}{c|cc} 0 & & \\ c_2 & c_2 & \\ \hline & b_1 & b_2 \end{array}$$

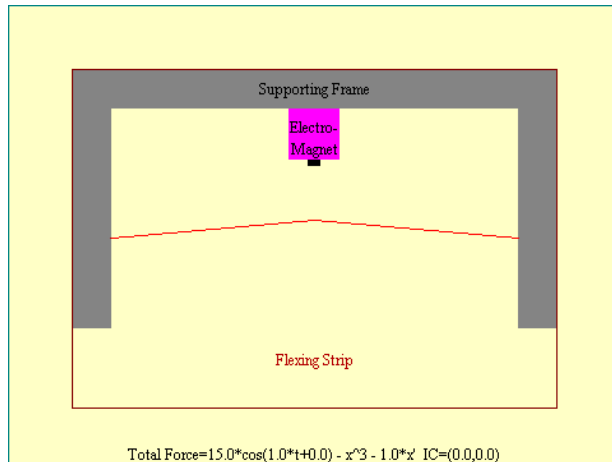

is used to solve (1). Show that the method can be written on the form (2). Now assume that  $h \leq h_{\text{max}}$  and show that  $\Phi$  satisfies the Lipschitz condition in  $y$ , with Lipschitz constant  $M$  that depends on the method coefficients  $c_2$ ,  $b_1$  and  $b_2$ , as well as  $L$  and  $h_{\text{max}}$ .

## Task 2

The Duffing oscillator is a much studied mathematical model. This can be described by the initial value problem

$$u'' + ku' - u(1 - u^2) = A \cos(\omega t). \quad (4)$$

In 1918, G. Duffing used this equation to describe a thin, flexible metal bar oscillating near an electromagnet. The constant  $k$  is the damping, while  $\omega$  and  $A$  are the frequency and the amplitude of the driving force from the electromagnet respectively. See <http://www.mcasco.com/pattr1.html> for more details.

- Start by transforming (4) to a system of two first-order differential equations.
- Calculate by hand (you are allowed to use a calculator) a single step with the improved Euler method (also known as Heun's method), setting  $k = 0.25$ ,  $A = 0.4$ ,  $\omega = 1.0$ ,  $u(0) = 0$ ,  $u'(0) = 0$ , and using step length  $h = 0.1$ .
- Implement the improved Euler method in MATLAB and use it to solve (4).
- Create a plot of the first component  $u$  along the  $x$ -axis and the second component  $u'$  along the  $y$ -axis (this is called a *phase plot*). Start with the same parameters as in **b**), but vary them and see what happens. You may use  $h = 0.01$ . Try integrating over quite long time intervals.
- Try several different initial values and plot the resulting integral curves to get a picture of what the curves look like. You can use the same values as above for  $k = 0.25$ ,  $A = 0.4$ ,  $\omega = 1.0$ .
- Finally, make an implementation where you replace improved Euler by RK4. Compare the results.

### Task 3

Kutta's method from 1901 is the most famous of all explicit Runge–Kutta pairs, given by the following Butcher tableau:

|               |               |               |               |               |
|---------------|---------------|---------------|---------------|---------------|
| 0             |               |               |               |               |
| $\frac{1}{2}$ | $\frac{1}{2}$ |               |               |               |
| $\frac{1}{2}$ | 0             | $\frac{1}{2}$ |               |               |
| 1             | 0             | 0             | 1             |               |
|               | $\frac{1}{6}$ | $\frac{1}{3}$ | $\frac{1}{3}$ | $\frac{1}{6}$ |

- a) Verify that the method has order 4 by checking all 8 order conditions.
- b) An alluring thought is to now find a new set of weights, say  $\hat{b}_s$  such that the accompanying method is of order 3, for error estimates and step length control. Try to find such a set of  $\hat{b}_s$ .

### Task 4

- a) Show that an explicit Runge–Kutta method with  $s$  stages maximally can be of order  $s$ . (Hint: Use  $y' = y$ ,  $y(0) = y_0$  as test equation.)
- b) Show that an explicit 3rd order Runge–Kutta method with 3 stages must satisfy

$$3a_{32}c_2^2 - 2a_{32}c_2 - c_2c_3 + c_3^2 = 0.$$

- c) Characterise all 3rd order explicit Runge–Kutta methods with 3 stages that satisfy  $a_{31} = 0$ , i.e.  $a_{32} = c_3$ . How many free parameters are there?
- d) Find all explicit methods of order 2 that have the same coefficients  $a_{ij}$  as the method above, and weights that simultaneously satisfy  $\hat{b}_3 = 0$ .

### Task 5

a) Find the eigenvalues of the matrix

$$M = \begin{pmatrix} -10 & -10 \\ 40 & -10 \end{pmatrix}.$$

b) Assume that you are to solve the differential equation

$$y' = My, \quad y(0) = y_0$$

using the improved Euler method. What is the largest step size  $h_{\max}$  you can use?

c) Solve the equation

$$y' = My + g(t), \quad 0 \leq t \leq 10$$

with

$$g(t) = (\sin(t), \cos(t))^T, \quad y(0) = \left( \frac{5210}{249401}, \frac{20259}{249401} \right)^T$$

by using `impEuler.m`. Choose step sizes a little smaller than and a little larger than  $h_{\max}$ . What do you observe?

### Task 6

The linear test equation

$$y' = \lambda y, \quad y(0) = y_0$$

has solution  $y(h) = e^z y_0$  where  $z = \lambda h$ . One step with a Runge–Kutta method gives  $y_1 = R(z)y_0$ . Thus, we can consider the stability function  $R(z)$  as an approximation of  $e^z$ . Will  $R(z)$  grow (absolutely) faster than  $e^z$ ? We can find this out by studying when  $|R(z)/e^z| > 1$ .

Rewrite the script `stab.m` so that it plots the region

$$\mathcal{A} = \{z \in \mathbb{C} \mid |R(z)/e^z| > 1\}.$$

Calculate the stability function for some of the Runge–Kutta methods you know and find  $\mathcal{A}$  for them. You may also draw the stability functions for the Gauss–Legendre methods (collocation methods of order  $2s$ ). These are given by:

$$\begin{aligned} s = 1, \quad R(z) &= \frac{1 + z/2}{1 - z/2}, \\ s = 2, \quad R(z) &= \frac{1 + z/2 + z^2/12}{1 - z/2 + z^2/12}, \\ s = 3, \quad R(z) &= \frac{1 + z/2 + z^2/10 + z^3/120}{1 - z/2 + z^2/10 - z^3/120}. \end{aligned}$$

The region  $\mathcal{A}$  is called an *order star*.
