If we are going to embark on a world of **Brave New Algebraic Geometry**, [BNAG] we have to understand is local-to-global principles

- How do we assemble local information?
- In particular: how do we paste vector bundles? (whose geometric interpretation in BNAG is still up for grabs)

We even want to consider what can be said while allowing singularities [and so the questions are not accessible through motivic methods even in OAG].

Topological K-theory is a cohomology theory and satisfies excision. If

$$\begin{array}{ccc} X_{12} & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ X_2 & \longrightarrow & X_0 \end{array}$$

is a (homotopy) cocartesian square of spaces, then

$$\begin{array}{ccc} K(X_{12}) & \longleftarrow & K(X_1) \\ \uparrow & & \uparrow \\ K(X_2) & \longleftarrow & K(X_0) \end{array}$$

is a homotopy cartesian square of spectra, illustrating that virtual bundles can be assembled from local data.

In AG one would consider a pushout square like

$$\begin{array}{ccc} X_{12} & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ X_2 & \longrightarrow & X_0 \end{array}$$

in schemes, and ask whether the corresponding square of algebraic K-theory spectra were homotopy cartesian.

Let us look at the affine case. Let

$$\mathcal{A} = \left\{ \begin{array}{ccc} A_0 & \longrightarrow & A_1 \\ \downarrow & & \downarrow \\ A_2 & \longrightarrow & A_{12} \end{array} \right\}$$

be a cartesian square of rings (corresponding in the commutative case to a cocartesian square

$$\mathrm{Spec}(\mathcal{A}) = \left\{ \begin{array}{ccc} \mathrm{Spec}(A_0) & \longleftarrow & \mathrm{Spec}(A_1) \\ \uparrow & & \uparrow \\ \mathrm{Spec}(A_2) & \longleftarrow & \mathrm{Spec}(A_{12}) \end{array} \right\}$$

of schemes).

To assure homotopy (co)cartesianness assume all arrows in \mathcal{A} surjective.

Let us look at the affine case. Let

$$\mathcal{A} = \left\{ \begin{array}{ccc} A_0 & \longrightarrow & A_1 \\ \downarrow & & \downarrow \\ A_2 & \longrightarrow & A_{12} \end{array} \right\}$$

be a cartesian square of rings (corresponding in the commutative case to a cocartesian square

Bass' program for higher K-theory rested on getting this right: he realized that the Whitehead groups K_1 could be built out of “clutching functions” so that excision seemed secure.

Bass' program for higher K-theory rested on getting this right: he realized that the Whitehead groups K_1 could be built out of “clutching functions” so that excision seemed secure.

at the heart of the matter: Milnor's theorem

Bass' program for higher K-theory rested on getting this right: he realized that the Whitehead groups K_1 could be built out of "clutching functions" so that excision seemed secure.

Theorem [Milnor]

Let \mathcal{A} be a cartesian square of rings where the vertical maps are surjections. Then the corresponding square of categories of finitely generated modules $\mathcal{P}_{\mathcal{A}}$ is a fiber square.

So, Milnor's theorem is not enough: that the square of exact categories is a fiber square does not guarantee that its K-theory will be homotopy cartesian.

Can one control this breakdown of excision?

First step in this direction came around 1980 when Guin-Waléry and Loday showed (with a slight reinterpretation) that if

$$\mathcal{A} = \left\{ \begin{array}{ccc} A_0 & \longrightarrow & A_1 \\ \downarrow & & \downarrow f_1 \\ A_2 & \xrightarrow{f_2} & A_{12} \end{array} \right\}$$

is a cartesian square of \mathbb{Q} -algebras with all maps surjective and $I_j = \ker\{f_j\}$, then the first nonvanishing obstruction group satisfies

$$\pi_2 \text{ifi}K(\mathcal{A}) \cong I_1/I_1^2 \otimes_{A_0 \otimes A_0} I_2/I_2^2 \cong \pi_1 \text{ifi}HC(\mathcal{A})$$

where *ifi* is the iterated fiber of a cube of spectra, and *HC* is cyclic homology.

The conjecture remained unresolved until recently when Cortiñas proved it using the techniques of Suslin and Wodzicki [Ann. Math. 92].

Theorem [Cortiñas, Inv. math. 06]

If \mathcal{A} is a cartesian square of \mathbb{Q} -algebras with vertical maps surjective, then the trace map induces an equivalence of spectra

$$ifiK(\mathcal{A}) \xrightarrow{\sim} ifiHC^-(\mathcal{A}) \xleftarrow{\sim} S^1 \wedge ifiHC(\mathcal{A}).$$

Considering a map of squares as a cube, Cortiñas theorem says that both the cubes

$$K(\mathcal{A}) \rightarrow HC^-(\mathcal{A}), \text{ and } S^1 \wedge HC(\mathcal{A}) \rightarrow HC^-(\mathcal{A})$$

are homotopy cartesian.

Theorem [Cortiñas, Inv. math. 06]

If \mathcal{A} is a cartesian square of \mathbf{Q} -algebras with vertical maps surjective, then the trace map induces an equivalence of spectra

$$ifiK(\mathcal{A}) \xrightarrow{\sim} ifiHC^-(\mathcal{A}) \xleftarrow{\sim} S^1 \wedge ifiHC(\mathcal{A}).$$

Considering a map of squares as a cube, Cortiñas theorem says that both the cubes

$$K(\mathcal{A}) \rightarrow HC^-(\mathcal{A}), \text{ and } S^1 \wedge HC(\mathcal{A}) \rightarrow HC^-(\mathcal{A})$$

are homotopy cartesian.

Outside characteristic zero, cyclic homology must of course be exchanged for topological cyclic homology TC :

Theorem [Geisser-Hesselholt, Inv. math. 06]

If \mathcal{A} is a cartesian square of rings with vertical maps surjective, then the cyclotomic trace map induces a cube

$$K(\mathcal{A}) \rightarrow TC(\mathcal{A})$$

which is homotopy cartesian after profinite completion.

Outside characteristic zero, cyclic homology must of course be exchanged for topological cyclic homology TC :

Theorem [Geisser-Hesselholt, Inv. math. 06]

If \mathcal{A} is a cartesian square of rings with vertical maps surjective, then the cyclotomic trace map induces a cube

$$K(\mathcal{A}) \rightarrow TC(\mathcal{A})$$

which is homotopy cartesian after profinite completion.

Since topological cyclic homology is open to attack with tools from stable homotopy theory, this makes calculations of K -theory possible.

Outside characteristic zero, cyclic homology must of course be exchanged for topological cyclic homology TC :

Theorem [Geisser-Hesselholt, Inv. math. 06]

If \mathcal{A} is a cartesian square of rings with vertical maps surjective, then the cyclotomic trace map induces a cube

$$K(\mathcal{A}) \rightarrow TC(\mathcal{A})$$

which is homotopy cartesian after profinite completion.

Since topological cyclic homology is open to attack with tools from stable homotopy theory, this makes calculations of K -theory possible. For instance, Geisser and Hesselholt have calculated the K -theory of the coordinate axes $\mathbf{F}_p[x, y]/xy$.

Since simplicial rings lie densely in connective S -algebras, one would expect that these results followed for connective S -algebras once one extended the results from discrete rings to simplicial rings.

Indeed this is true, and such a proof has been worked out. However, there is a quicker proof, which I will present shortly.

Reason for wanting the long proof: Simplicial rings give hope of uncovering the right homotopical conditions on the categories of modules (surjectivity is not the right condition).

Theorem [D, Kittang]

If \mathcal{A} is a cartesian square of connective \mathbf{S} -algebras with vertical maps 0-connected, then the cyclotomic trace map induces a homotopy cartesian cube

$$K(\mathcal{A}) \rightarrow TC(\mathcal{A}).$$

Theorem [D, Kittang]

If \mathcal{A} is a cartesian square of connective \mathbf{S} -algebras with vertical maps 0-connected, then the cyclotomic trace map induces a homotopy cartesian cube

$$K(\mathcal{A}) \rightarrow TC(\mathcal{A}).$$

Note:

The circulating preprint only claims this after profinite completion, but using Goodwillie's model for integral TC and the techniques of Suslin/Wodzicki and Geisser/Hesselholt, Kittang has worked out the integral statement.

Let F be the homotopy fiber of the p -completion of the cyclotomic trace $K \rightarrow TC$.

The theorem is equivalent to the claim that $F(\mathcal{A})$ is homotopy cartesian, that is, F satisfies excision.

Let F be the homotopy fiber of the p -completion of the cyclotomic trace $K \rightarrow TC$.

The theorem is equivalent to the claim that $F(\mathcal{A})$ is homotopy cartesian

The result is easily proven from
