PARAMETRIC LIFETIME ANALYSIS IN MINITAB

The screenshot shows the Minitab software interface. The menu bar is visible at the top, and the 'Stat' menu is open, displaying various statistical analysis options. The 'Reliability/Survival' option is highlighted. A sub-menu for 'Reliability/Survival' is open, showing options like 'Demonstration Test Plans...', 'Estimation Test Plans...', 'Accelerated Life Test Plans...', 'Distribution Analysis (Right Censoring)...', 'Distribution Analysis (Arbitrary Censoring)...', 'Parametric Growth Curve...', 'Nonparametric Growth Curve...', 'Accelerated Life Testing...', 'Regression with Life Data...', and 'Probit Analysis...'. The 'Parametric Distribution Analysis...' option is highlighted with a gray selection box. Below the menu, a worksheet titled 'Worksheet 1 ***' is displayed, showing a grid of columns labeled C1 through C17 and rows numbered 1 to 14. The status bar at the bottom indicates 'Perform parametric analysis with no/right censoring', 'Editable', '20:25', and shows the taskbar with other application icons.

DATA OPTIONS

RIGHT CENSORING:

Y_i	δ_i
Observed time	Cens. status 1: Lifetime 0: Censoring

ARBITRARY CENSORING:

Start variable A_i	End variable B_i	
1.7	1.7	Exact lifetime 1.7
2.0	*	Right censoring at time 2.0, i.e. lifetime is > 2.0
*	0.5	Left censoring at time 0.5, i.e. lifetime is < 0.5
1.0	1.5	Interval censoring: Lifetime between 1.0 and 1.5

LIKELIHOOD CONTRIBUTION

Obs. type	Start variable A_i	End variable B_i	Likelihood contribution
Exact lifetime	1.7	1.7	$f(1.7; \theta)$
Right censoring	2.0	*	$1 - F(2.0; \theta)$
Left censoring	*	0.5	$F(0.5; \theta)$
Interval censoring	1.0	1.5	$F(1.5; \theta) - F(1.0; \theta)$

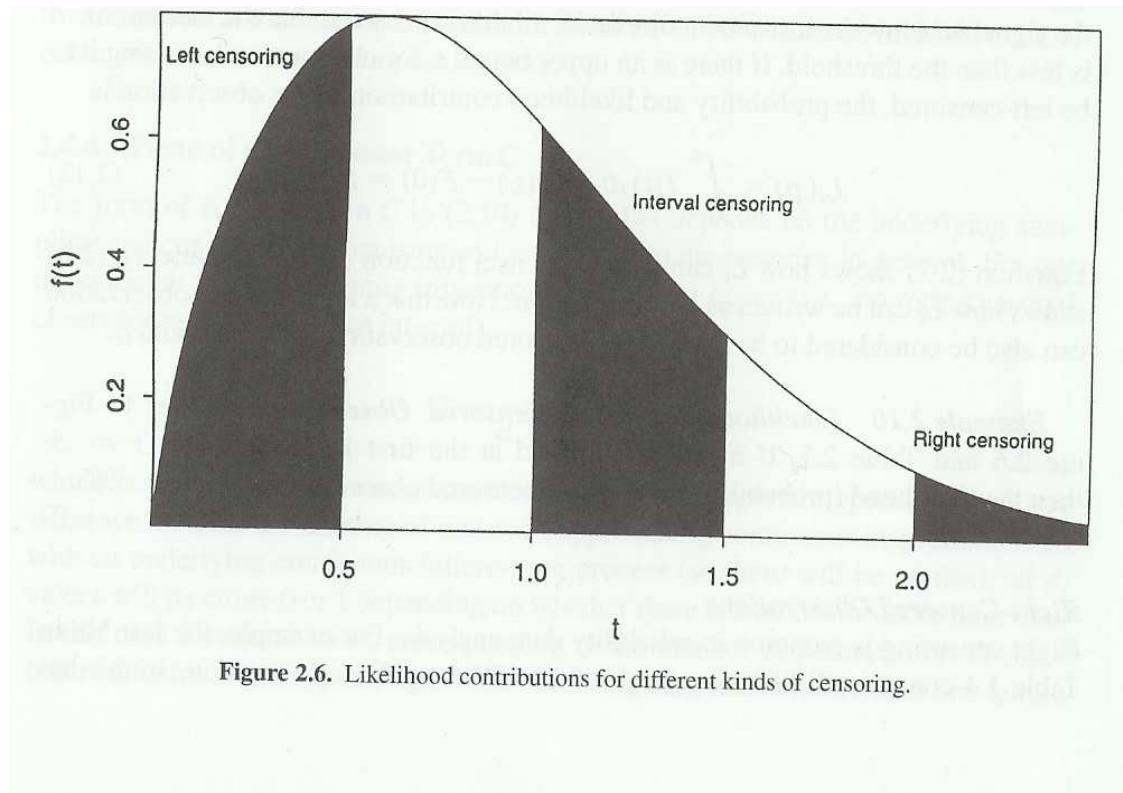

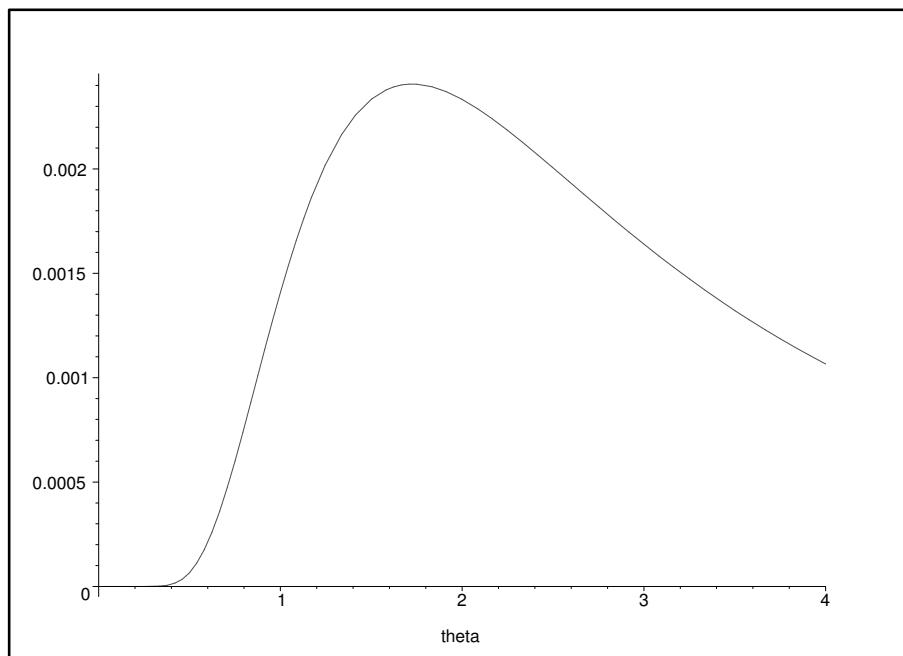

Figure 2.6. Likelihood contributions for different kinds of censoring.

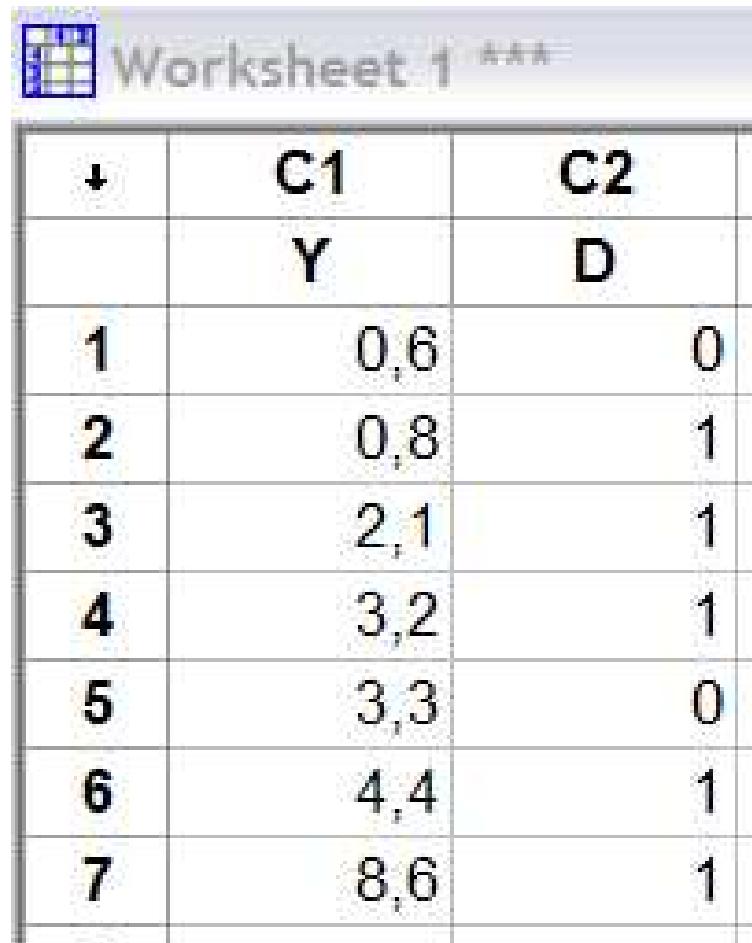

LIKELIHOOD FOR MODEL $f(t; \theta) = (1/\theta)e^{-t/\theta}$

$$L(\theta) = \left(\frac{1}{\theta}e^{-1.7/\theta}\right) \cdot \left(e^{-2.0/\theta}\right) \cdot \left(1 - e^{-0.5/\theta}\right) \cdot \left(e^{-1.0/\theta} - e^{-1.5/\theta}\right)$$

Maximum likelihood estimate: $\hat{\theta} = 1.725$

EXAMPLE: RIGHT CENSORED DATA

The screenshot shows a Microsoft Excel spreadsheet with the title "Worksheet 1" at the top. The data is organized into three columns: a row header column labeled with numbers 1 through 7, a column labeled "C1" containing values 0,6; 0,8; 2,1; 3,2; 3,3; 4,4; and 8,6, and a column labeled "C2" containing values 0; 1; 1; 1; 0; 1; and 1. The cells are separated by thin vertical and horizontal lines.

	C1	C2
	Y	D
1	0,6	0
2	0,8	1
3	2,1	1
4	3,2	1
5	3,3	0
6	4,4	1
7	8,6	1

Method – Probability Plot for Uncensored/Right Censored Data

[main topic](#)

Probability plots are based on a scheme that plots the observed failure times (or a transformation of the failure times) on the x-axis vs. the estimated cumulative probabilities (p) on the y-axis. The cumulative probabilities are transformed. Transformations of both the x and y data are needed to ensure that the plotted y values are a linear function of the plotted x values. To help assess the linearity of the plotted data, a fitted line is also drawn on the probability plots. The table below shows how the actual x and y plot points are constructed:

Distribution	x coordinate	y coordinate
Weibull	$\ln(\text{failure time})$	$\ln(-\ln(1 - p))$
Extreme value	failure time	$\ln(-\ln(1 - p))$
Exponential	failure time	$-\ln(1 - p)$
Normal	failure time	$\Phi^{-1}(p)$
Lognormal basee	$\ln(\text{failure time})$	$\Phi^{-1}(p)$
Lognormal base10	$\log_{10}(\text{failure time})$	$\Phi^{-1}(p)$
Logistic	failure time	$\ln\left(\frac{p}{1-p}\right)$
Loglogistic	$\ln(\text{failure time})$	$\ln\left(\frac{p}{1-p}\right)$

where

$\Phi^{-1}(p)$ = value of standard normal distribution, Z, such that prob $(Z \leq \Phi^{-1}(p)) = p$

$\ln(x)$ = natural log of x

$\log_{10}(x)$ = log base 10 of x

Minitab estimates the cumulative probabilities (p) using the Default, Modified Kaplan-Meier, Herd-Johnson, or Kaplan-Meier method. The Default method is the normal score for uncensored data; the modified Kaplan-Meier method for censored data. Each of these methods generates nonparametric estimates of $F(t)$, the cumulative distribution function for the random variable T, which is time to failure.

Note If the largest observation is uncensored, the Kaplan-Meier method results in $p=1$ for the largest uncensored observation. In this case, the Kaplan-Meier estimate for the largest observation results in a number that cannot be used in the plot. This problem is corrected by recalculating the largest p as 90% of the distance between the prior p and 1.

This table displays the differences among the methods. For a sample of n observations, let $x(1), x(2), \dots, x(n)$ be the order statistics, or the data ordered from smallest to largest. Then i is the rank of the ith ordered observation $x(i)$. The formulas are as follows:

For uncensored data...

This method ...	Uses this equation
Normal score (default)	$\frac{i - 3/8}{n + 1/4}$
Modified Kaplan-Meier	$\frac{i - 1/2}{n}$
Herd-Johnson	$\frac{i}{n + 1}$
Kaplan-Meier	$\frac{i}{n}$

For censored data...**This method...**

Modified Kaplan-Meier (default)

Uses this equation

$$p_i = 1 - \frac{(1 - p'_i) + (1 - p'_{i-1})}{2}$$

where p'_i is the p_i from the Kaplan-Meier estimate and $p'_0 = 0$.

Herd-Johnson estimate

$$p_i = 1 - \prod_{j=1:i} \frac{(n-j+1)}{(n-j+2)} \delta_j$$

Kaplan-Meier product limit estimate

$$p_i = 1 - \prod_{j=1:i} \frac{(n-j)}{(n-j+1)} \delta_j$$

where

 $\delta_j = 0$ if the j th observation is censored1 if the j th observation is uncensored

If there are tied failure times in the data, either all points (default), the average (median), or the maximum of the tied points is plotted. If the tie involves failures and suspensions, the failures are considered to occur before the suspensions.
